Abstract: These days pozzolans are utilized boundlessly in common undertakings. Pozzolan is a characteristic or fake material containing dynamic silica that expansion the quality and improves a few properties of cement. In this study for exploring some significant properties of solid, silica smoke and fly debris was utilized in substitution of concrete in various loads. Solid creations were made with water-concrete proportion of 0.45 and restored under similar conditions. The primary focal point of this review is to research the individual and joined impact of utilizing Pozzolan on mechanical properties, porousness and shrinkage of cement. The mechanical properties of cement in compressive and twisting quality at the age of 7, 28 and 90 days, were assessed. Penetrability was explored with the water assimilation test. The drying shrinkage of cement was checked for 90 days. Examining Electron Microscopy (SEM) pictures was utilized in solid concrete based lattice morphology. The outcomes indicated that the expansion of pozzolan expands the mechanical quality and decrease penetrability and increment the drying shrinkage in certain blends.

Keywords: Silica Fume; Fly Ash; Mechanical; Permeability, Compression, SEM.

I. Introduction

Energy crises and the need to save the energy-making materials in producing productions like cement has caused to make a full-scale effort in producing economically and improving the quality in global scale. One of the effective steps toward this problem is using both natural and artificial Pozzolanic materials in cement. Using these materials as a replacement to a portion of cement, not only reduces the price of concrete but also improves the properties of fresh and hardened concrete. By far many researches are done worldwide on different kinds of Pozzolans. As an example, micro silica and fly ash can be named that have proper Pozzolanic characteristics and in increasing the strength and durability of concrete have an effective role. Knowing the fact that permeability and shrinkage are the key properties of concrete in studying its long-term behavior and they have a tight relation with its durability, using mineral additives and industrial Pozzolanic residues in order to improve the long-term functionality and increase the strength of concrete was the research subject of many experts in this field and is resulted to vast industrial application of some of these materials. The researches have shown that replacement of a portion of cement with some Pozzolanic additive materials decreases the hydration temperature and its resulting crack and also reduces the shrinkage. Stable construction with the aim of saving energy, resources and costs and also reducing the destructive environmental effects are some advantages of using these kinds of additives [1-6].

Silica fume (SF) that is of industrial additives is actually dust emissions from the chimneys of factories producing silicon and silicon alloys, such as Ferrosilice in electric arc furnaces. Its reaction with massive and high porosity limestone crystals and converting them to calcium silicate hydroxide gel C-S-H improves the bond between cement paste and aggregate that is used as a cement replacement in concrete production [7-9]. Bhanja and Sengupta investigated the effect of silica fume on concrete tensile strength, therefore different water-cement ratio (0.26 to 0.42) as well as replacement of silica fume with cement at different levels (0 to 30%) were considered [10]. Their results showed that the presence of silica fume in the mixture caused a significant increase in tensile and compression strength. Fly ash is a material with very fine particles (particles as cement) that is obtained from the waste of combustion of coal powder in thermal power plants [11-13]. The effect of FA, GGBFS and SF as a supplement mixture of cement in binary, ternary and quaternary combination was investigated by Gesoglu and Ozbay on fresh and hardened self-compacting concrete properties [14]. They reported that a ternary mixture of cement with FA and SF has higher compressive strength compared to the binary mixture with the same amount of replacement. Shrinkage is the volume change caused by losing the buried water in concrete due to evaporation as a result of being exposed to dry environments. This evaporation depends on relative humidity, temperature, water-cement ratio, size and shape of the sample. Shrinkage of concrete with constant water-cement ratio of 0.35 was examined by Katri and Sirivatnanon [15]. It was found that replacement of 10% of the cement with silica fume increases the shrinkage at early ages and reduces it in the long term. Sadr and Fasihi reported an increase in shrinkage in a study on the silica fume cement composites and nano silica [16]. Also in replacement of slag with cement due to the small amount of calcium hydroxide, this effect reduces to a large extent compared to replacement of silica fume with cement. Also, according to investigations of Jianyong and Yan on three different

kinds of concrete containing silica fume and slag individually and combinationally, with water-cement ratio of 0.26, it was shown that drying shrinkage at early ages was the same. After 28 days, the amount of shrinkage changed so that at the age of 180 days, the amount of control mix design,

30% of slag and the combination of 10% silica fume with 30% slag were 220, 96 and 127 micrometers, respectively. Calcium hydrate formation due to pozzolanic reaction of mineral additives that have been replaced by cement can be the reason to reduce the shrinkage. Knowing the permeability of concrete for structures that are subject to severe environmental change such as melting, freezing and chemical attacks are of great importance. Thus, molecular and ion permeability of concrete, acts a special role in being affected by the environment and the loading capacity of the structure during decades of its age. Hooton studied the permeability of concrete containing silica fume and stated that permeability decreased with the addition of silica fume [18]. Permeability of control mixture was 1.8×10^{-14} meters per second while for the concrete mixture containing 10% silica fume, it was less than 1×10^{-17} meter per second.

In this study, the investigation on some of the important properties of concrete containing silica fume and fly ash as a cement materials replacement in different quantities were discussed. Concrete mixtures were made with water-cement ratio of 0.45. The main focus of this study was to evaluate the effect of individual and combined use of pozzolan on mechanical properties, permeability and shrinkage of the concrete. Permeability was investigated with the water absorption test. The drying shrinkage of concrete was monitored for 90 days. The mechanical properties of concrete in compressive and bending strength at the age of 7, 28 and 90 days, were evaluated. Scanning Electron Microscope (SEM) images was used in concrete cement based matrix morphology. The results showed that the addition of pozzolan increases the mechanical strength and reduce permeability and increase the drying shrinkage in some mixtures.

II. Experimental Program

2.1. Materials

In this study, type 1-425 Khamse Zanjan cement in accordance with ASTM C150 standard was used, silica fume of Iran Ferrosilicon company in accordance with ASTM C1240 standard and fly ash in accordance with ASTM C618 standard in mix design was used. Its physical and chemical properties are given in tables 1 and 2, respectively. In order to achieve proper slump (70 ± 20) super plasticizer with the brand of P10-3R was bought from the Shimi Sakhteman Company. Aggregates used to produce the mixture of crushed gravel with a maximum size of 19 mm and a density of 2650 kg/m³ and natural sand with density of 2600 kg/m³ that was in accordance with the ASTM C33 standard.

Table 1. Physical properties of cementitious materials

Item	Specific surface (cm ² /gr)	Density ()	Initial setting time (min)	Final setting time (min)
Cement	3100	3.15	110	170
Silica fume	6500	2.2	-	-
Fly Ash	3670	2.5	-	-

Table2. Chemical composition of cementitious materials (%)

Item	CaO	SiO ₂	Al ₂ O ₃	Fe ₂ O ₃	MgO	K ₂ O	Na ₂ OSO ₃	L.O.I	
Cement	64.37	21.08	5.36	3.64	2	0.82	0.5	2.1	0.9
Silica Fume	1.5	90	1	2	2	0	0	0	3.5
Fly Ash	8.6	59.3	23.4	4.8	0.6	-	3.2	0.1	-

2.2. Preparing and curing of mix designs

First, aggregate in state of saturated surface dry (SSD) was poured in the mixer. Then cement powder materials and some water is added and the remaining water was gradually added to the mixture. Mixing time was between three to four minutes. Concrete compacting was achieved in the laboratory using a vibrating table. Mix Designs of this research are shown in Table 3. According to ASTM C192, after 24 hours of curing the specimens in the mold with a plastic cover, they were exported and placed in a saturated lime water layer with standard temperature until the day they were tested.

Table 3. Mix designs

Mix Design Name	W/B	Kg/m ³					S.P
		Cement	Silica fume	Fly Ash	Fine agg	Coarse agg	
control	0.45	400	0	0	944	871	0.7
F15	0.45	340	0	60	939	867	0.45
F25	0.45	300	0	100	935	863	0.3
S10	0.45	360	40	0	937	865	1.2
S25	0.45	300	100	0	925	854	1.45
S5F5	0.45	360	20	20	939	867	0.9

III. Results and Discussion

3.1. Compressive Strength Test

The tests were executed at the ages of 7, 28 and 90 days on the 10 cm cubic samples. The results are shown in Figure 2. According to the results, the increase in strength over time can be observed in all samples. In samples containing fly ash with cement, compressive strength in comparison with control mix design is not increased at the age of 7 and 28 day. At the age of 7 and 28 the control mix design showed the maximum strength but at 90 days age, the FA15 mix design had 40 MPa of compressive strength that showed 17.6% enhancement compared to control mix design. Also at the age of 90 days, all samples showed more strength with respect to control mix design. In individual mixtures, combination of silica fume and cement, compressive strength at ages of 28 and 90 days significantly increased, so this increase is respectively 29% and 19%. According to studies of some researchers [15, 19] the presence of silica fume due to pozzolanic reaction with calcium hydroxide in the cement paste and calcium silicate hydroxide gel formation causes enhancement in the strength. Silica fume can improve the microstructure and mechanical strength of concrete. Ultrafine particles of fume by filling voids in the cement

paste and having reaction with the calcium hydrates in the paste, improve compacting and physical and chemical properties of concrete [20]. According to the results, the rate of increase in compressive strength in mix designs containing fly ash in comparison with mix designs containing silica fume individually is less. The slower pozzolanic reaction of fly ash could cause this issue. In combinatorial mix designs increasing the amount of pozzolan caused improvement in strength and at older ages, it is more considerable.

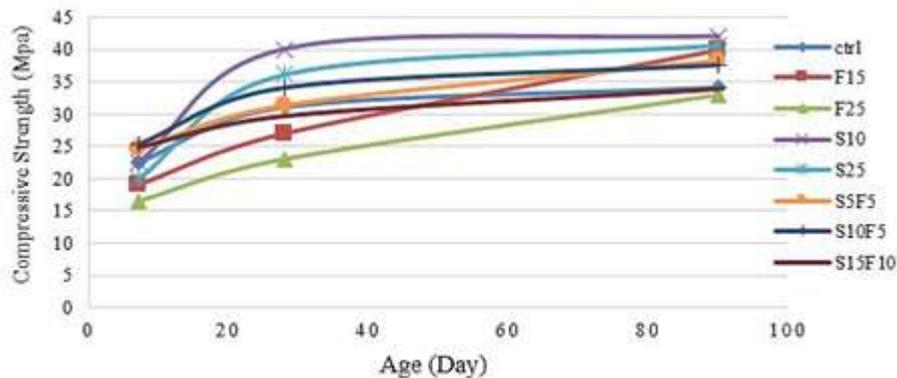

Figure 2. Compressive strength of concrete mixtures

3.2. Flexural Strength Test

The test was done according to ASTM C78 for three points on cubic specimens with 7×7×28 cm dimensions at ages 7, 28 and 90 days. Figure 3 shows the results of flexural strength in different replacement percentages of silica fume and fly ash individually and in combination. According to the results, the addition of pozzolans increased flexural strength. In the mixtures containing up to 15% of fly ash flexural strength increased and after that it decreased and the maximum of flexural strength values at 28 and 90 days was 7.54 and 7.8 MPa that related to F15 mix design. It seems silica fume has more impact on the flexural strength so that in all of the replacement percentages the flexural strength is higher than control mixture at all ages. In mixtures containing silica fume individually maximum amount of flexural strengths at the age of 7, 28 and 90 days, respectively were 7.12, 10.14 and 11 MPa and they were related to S10 mix design which has respectively 11%, 36% and 44% improvement in strength with respect to control mix design. Results of combinatorial mix designs also shows an increase in flexural strength compared to the control mix design.

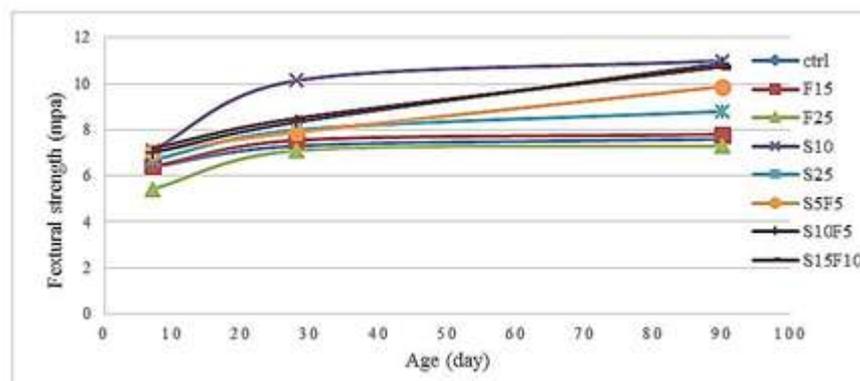

Figure 3. Flexural strength of concrete mixtures

3.3. Final Water Absorption Test

The water absorption was tested according to ASTM C642 standard on cubic samples at the age of 28 and 90 days. The importance of this test is that its results indicates the volume of capillary and large pores in a cement composite that is an important criterion in assessing the influence of destructive ions. The results of water absorption test were determined based on the average results of three samples are shown in Figure 4. The results show that by increasing the amount of pozzolanic materials replacement of cement, water absorption reduction of concrete is significant. The addition of fly ash up to 10% caused 18.5% reduction in water absorption. Also with increasing replacement of silica fume up to 25%, water absorption had downward trend up to 46%. Compared with fly ash, silica fume can impressively reduce the amount of water absorption and by increasing the replacement rate, water absorption is reduced. In mixed pozzolan mixtures in high percentage of silica fume and fly ash water absorption reduction is clear.

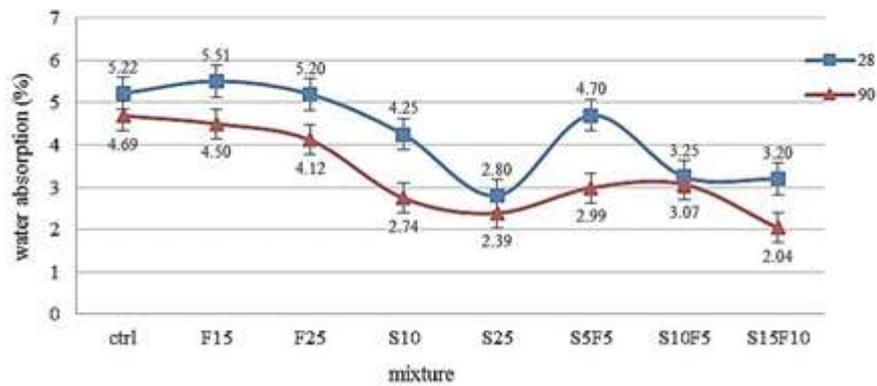

Figure 4. Water absorption of concrete mixtures

3.4. Morphology

Scanning Electron Microscope (SEM) is an effective way to evaluate the morphology of hydrated cement-based products. According to Figure 5, some of the pores caused by the crystallization of excess lime are clearly visible and due to the absence of mineral additives, the porosity of the paste is obvious. It indicates that the paste matrix is not significantly compressed. In comparison with the control mixtures, the mixtures containing pozzolans showed more uniformity, compacting and improve interfacial transition zone (ITZ). The concrete containing 10% silica fume and 15% fly ash, showed most uniform microstructure and compacting in cement matrix.

3.5. Shrinkage Test

Shrinkage was tested according to ASTM C157 on the cubes with 7×7×28 cm dimensions. The specimens extracted from the mold and after 24 hours under ambient conditions for drying shrinkage by the available strain gauge (with an accuracy of a thousandth of a millimeter) were evaluated for 90 days. The average results of measurements were performed on two samples. Shrinkage has a great importance to study the long-term durability and performance of concrete structures. In fact, the importance of shrinkage is that it can be a source of cracking, reducing resistance, redistribution of stress and in some cases also led to the destruction of the structure. The results of shrinkage are shown in Figure 5. The results indicated that the addition of silica fume is significantly affected drying shrinkage of concrete. The greatest change in the amount of shrinkage is related to mixtures containing silica fume. The shrinkage values have increased compared to the control mixture. The effect of silica fume can be a cause of this issue. The use of mineral additives in concrete mixture changes pore microstructure and geometry, change in capillary pore structure causes a change in shrinkage, Using silica fume increase drying shrinkage of concrete and it can be because of the pozzolanic behavior of silica fume [21]. The mixtures containing fly ash showed reduction in the rate of shrinkage compared to control mix design. During first days the changing rate of S10 and S25 mixtures was more than other mixtures that indicates extreme pozzolanic activation of silica fume on early ages.

IV. Conclusion

Evaluation of mechanical properties (compressive strength, flexural strength), final water absorption, morphology and drying shrinkage of concrete with silica fume and fly ash at different curing ages was presented in this paper. The following conclusions were extracted:

- Based on experiments, it can be concluded the silica fume have significant superiority to fly ash. Advantage of silica fume as a perfect pozzolan at least for the first 3 months of concrete age can be clearly concluded from the results. Also the high percentage of silica as a factor of impermeability in the fume and its active effect on reduction of lime and increasing the amount of C-S-H and concrete's structural compacting improvement make the silica fume an effective additive for concrete.
- The presence of pozzolanic material in concrete mixtures has been increased compressive and flexural strengths. The presence of silica in binary mixtures increases the strength of all ages. Fly ash in old age has a high compressive strength of the concrete is witnessed. In combine mixture minor pozzolanic materials increased resistance is also present.as well as addition of minerals pozzolanic reduced water absorption.
- Mineral admixtures can improve microstructure as well as compressive strength. Mineral admixtures enhance microstructure mainly results from micro aggregate filling and the pozzolanic effect, fine particles bridge the gaps between cement particles, hydration products, matrix and aggregates, so pore structure becomes denser.
- Addition of silica fume increased the drying shrinkage of concrete but using fly ash decreased it.
